# **Structure Learning Algorithms for Chain Graphs**

Master's thesis  
in MATHEMATICS

Supervisor:  
**John Noble, PhD.**  
Institute of Applied Mathematics and Mechanics

April 2017

### **Supervisor's statement**

Hereby I confirm that the present thesis was prepared under my supervision and that it fulfils the requirements for the degree of Master of Mathematics.

Date

Supervisor's signature

### **Author's statement**

Hereby I declare that the present thesis was prepared by me and none of its contents was obtained by means that are against the law. The thesis has never before been a subject of any procedure of obtaining an academic degree. Moreover, I declare that the present version of the thesis is identical to the attached electronic version.

# Chapter 1

## Introduction

The purpose of this project is to present algorithms for learning conditional independence structure of joint probability distributions represented by chain graphs. This is a special case of learning probabilistic graphical models which provides convenient representation of factorisation probability distribution using graphs. Two most common classes of probabilistic graphical models (PGMs) are Bayesian Networks where PGM is represented by directed acyclic graph and Markov Fields where PGM is represented by undirected graph. Chain graphs is a class of graphs that does not contains cycles (formal definition in 2.1.9). It contains both directed and undirected edges in graph representation hence it is natural generalization of Bayesian Networks and Markov Fields. Such a generalization was needed because of limitation of Markov Fields and Bayesian Networks. An edge in a Markov Field model represent that there is a correlation between two random variables but it does not specify what type of correlation it is. On the other hand Bayesian Network models contains only directed edges which represents only cause-effect relationships without possibility of existence of mutual correlation between two random variables. [TO BE CHANGED] In this paper we present one algorithm for learning chain graphs and one algorithm for learning undirected graphical models. Both algorithms are based on idea of graph decomposition which suppose to decrease complexity of algorithms. [/TO BE CHANGED]

## Chapter 2

# Preliminaries

### 2.1. Graph Theory Terminology

This section provides definitions of graph theory objects required for completeness of further sections. In this section, when is not mention different,  $V$  is default notation for set of graph's vertices and  $E$  is default notation for set of graph's edges.

**Definition 2.1.1. (Undirected edge)**

For vertices  $u, v \in V$  we say that there is an undirected edge between vertices  $u$  and  $v$  if  $(u, v) \in E$  and  $(v, u) \in E$ . Undirected edge between  $u$  and  $v$  is marked as  $u - v$ .

**Definition 2.1.2. (Directed edge)**

For vertices  $u, v \in V$  we say that there is a directed edge from vertex  $u$  to vertex  $v$  if  $(u, v) \in E$  and  $(v, u) \notin E$ . Directed edge from  $u$  to  $v$  is marked as  $u \rightarrow v$ .

**Definition 2.1.3. (Skeleton)**

Skeleton of graph  $G = (V, E)$  is a graph  $G' = (V', E')$  where  $V = V'$  and the set of edges  $E'$  is obtained by replacing directed edges of set  $E$  by undirected edges.

**Definition 2.1.4. (Route)**

A route in graph  $G = (V, E)$  is a sequence of vertices  $(v_0, \dots, v_k)$ ,  $k \geq 0$ , such that

$$(v_{i-1}, v_i) \in E \quad \text{or} \quad (v_i, v_{i-1}) \in E$$

for  $i = 1, \dots, k$ . The vertices  $v_0$  and  $v_k$  are called terminals. A route is called descending if  $(v_{i-1}, v_i) \in E$  for  $i = 1, \dots, k$ . Descending route from  $u$  to  $v$  is marked as  $u \mapsto v$ .

**Definition 2.1.5. (Path)**

A route  $r = (v_0, v_1, \dots, v_k)$  in graph  $G = (V, E)$  is called a path if all vertices in  $r$  are distinct.

**Definition 2.1.6. (Complex)**

A path  $\pi = (v_1, v_2, \dots, v_k)$  in graph  $G = (V, E)$  is called complex if

1.  $v_1 \rightarrow v_2$
2.  $\forall_{i \in \{2, 3, \dots, k-2\}} v_i - v_{i+1}$
3.  $v_{k-1} \leftarrow v_k$
4. There is not additional edges in graph  $G$  for vertices in path  $\pi$ .

Vertices  $v_1$  and  $v_k$  are called *parents of the complex*, set of vertices  $\{v_2, v_3, \dots, v_{k-1}\}$  is called *region of the complex* and number  $k - 2$  is the *degree of the complex*.

Next we define extended version of moral graphs. In Bayesian Networks moral graph is an undirected graph obtained from the original graph by adding undirected edges for not connected parents of the same child and then transform all edges into undirected edges. In case of chain graphs there can be situation when there are not connected parents of connected children (see 2.1). This situation can be interpreted as immoral and to be moralized a connection between parents are required.

**Example 2.1.1. (Immortality in chain graph)**

Figure 2.1: Immortality in chain graph

**Definition 2.1.7. (Moral Graph)**

Let  $G = (V, E)$  be a graph. A moral graph  $G^m = (V, E^m)$  of graph  $G$  is a graph obtained by firstly join parents of complexes in graph  $G$  and then replace all edges by undirected edges.

**Definition 2.1.8. (Cycle)**

A route  $r = (v_0, v_1, \dots, v_k)$  in graph  $G = (V, E)$  is called a *pseudocycle* if  $v_0 = v_k$  and a cycles if further route is a path and  $k \geq 3$ .

A graph with only directed edges is called an *undirected graph*. A graph without directed cycles and with only directed edges is called a *directed acyclic graph* (DAG).

**Definition 2.1.9. (Chain graph)**

A graph  $G = (V, E)$  is called a *chain graph* if it does not have directed (pseudo) cycles.

**Definition 2.1.10. (Section)**

A subroute  $\sigma = (v_i, \dots, v_j)$  of route  $\rho = (v_0, \dots, v_k)$  in graph  $G$  is called *section* if  $\sigma$  is the maximal undirected subroute of route  $\rho$ . That means  $v_i - \dots - v_j$  for  $0 \leq i \leq j \leq k$ . Vertices  $v_i$  and  $v_j$  are called *terminals of section  $\sigma$* . Further vertex  $v_i$  is called a *head-terminal* if  $i > 0$  and  $v_{i-1} \rightarrow v_i$  in graph  $G$ . Analogically vertex  $v_j$  is called a *head-terminal* if  $j < k$  and  $v_j \leftarrow v_{j+1}$  in graph  $G$ .

A section with two head-terminals is called *head-to-head* section. Otherwise the section is called *non head-to-head*. For a given set of vertices  $S \subset V$  in graph  $G$  and section  $\sigma = (v_i, \dots, v_j)$  we say that section is *hit by  $S$*  if  $\{v_i, \dots, v_j\} \cap S \neq \emptyset$ . Otherwise we say that section  $\sigma$  is *outside set  $S$* .

**Definition 2.1.11. (Intervention)**

A route  $\rho$  in graph  $G = (V, E)$  is *blocked* by a subset  $S \subset V$  of vertices if and only if there exists a section  $\sigma$  of route  $\rho$  such that one of the following conditions is satisfied.

1. Section  $\sigma$  is head-to-head with respect to  $\rho$  and  $\sigma$  is outside of  $S$ .

2. Section  $\sigma$  is non head-to-head with respect to  $\rho$  and  $\sigma$  is hit by  $S$ .

**Example 2.1.2. (Graph definitions)**

Based on the following two graphs (figures 2.2 and 2.3) we present examples of above defined definitions. Let graph presented in figure 2.2 be denoted as  $G$ . In graph  $G$  as example of descending route is  $(A, B, C, D)$  and example of non-descending route is  $(D, E, F, G)$ . Graph  $G$  contains two complexes. Complex  $(A, B, C, D, E)$  is of degree equal to 3 and the other one  $(F, G, H, I)$  is of degree equal to 2. Graph  $G$  contains one cycle  $(I, J, K, I)$ . The Route  $(F, G, H, I)$  in graph  $G$  contains section  $(G, H)$  which is head-to-head section.

Figure 2.2: Example graph

Graph presented in figure 2.3 is moral graph of graph  $G$ . Additional undirected edges  $A - E$  and  $F - I$  are the result of connecting parents of complexes in the original graph  $G$ .

## 2.2. Graphical Model Terminology

Our main goal is to find an conditional independence structure of given joint probability distribution, hence we start from recalling definition of conditional independence.

**Definition 2.2.1. Conditional Independence**

Let  $(X_1, X_2, \dots, X_n)$  be a random vector over probability space  $(\Omega, \mathcal{F}, \mathbb{P})$ . We say that random vectors  $X_A = \{X_a \mid a \in A\}$  and  $X_B = \{X_b \mid b \in B\}$  are conditional independent given  $X_S = \{X_s \mid s \in S\}$  when for all  $A_1, A_2, A_3 \in \mathcal{F}$

$$\mathbb{P}(X_A \in A_1, X_B \in A_2 \mid X_S \in A_3) = \mathbb{P}(X_A \in A_1 \mid X_S \in A_3) \mathbb{P}(X_B \in A_2 \mid X_S \in A_3) \quad (2.1)$$

where  $A, B, S \subset 1, 2, \dots, n$ . Conditional independence of  $X_A$  and  $X_B$  given  $X_S$  is denoted as  $X_A \perp\!\!\!\perp X_B \mid X_S$ .

The following definition of c-separation is an analogical version of d-separation, used in Bayesian Networks, for chain graphs. This definition was introduced by Studeny and Bouckaert in [4]. The notation c-separation is short of "chain separation" and it is written in this form to present analogy to definition of d-separation.

Figure 2.3: Moral graph of graph in figure 2.2

**Definition 2.2.2. (c-separation)**

Let  $G = (V, E)$  be a chain graph. Let  $A, B, S$  be three disjoint subsets of the vertex set  $V$ , such that  $A$  and  $B$  are nonempty. We say that  $A$  and  $B$  are *c-separated* by  $S$  on  $G$  if every route within one of its terminals in  $A$  and the other in  $B$  is blocked by  $S$ . We call  $S$  a *c-separator* for  $A$  and  $B$  and mark as  $\langle A, B \mid S \rangle_G^{sep}$ .

**Definition 2.2.3. (faithfulness)**

Let  $G = (V, E)$  be a chain graph with random variables  $X_v$  associated with vertex  $v \in V$ . Let note domain of random variable  $X_v$  as  $\mathcal{X}_v$ . A probability measure  $\mathbb{P}$  defined on  $\prod_{v \in V} \mathcal{X}_v$  is faithful with respect to  $G$  if for any triple  $(A, B, S)$  of disjoint subsets of  $V$  where  $A$  and  $B$  are non-empty we have

$$\langle A, B \mid S \rangle_G^{sep} \iff X_A \perp\!\!\!\perp X_B \mid X_S \quad (2.2)$$

In the same setup a probability measure  $\mathbb{P}$  is called *Markovian* with respect to  $G$  if

$$\langle A, B \mid S \rangle_G^{sep} \implies X_A \perp\!\!\!\perp X_B \mid X_S \quad (2.3)$$

The following theorem from Frydenberg's paper [1] provides convenient tool for testing if two given chain graphs are the same in respect to Markov equivalent class.

**Proposition 2.2.1. (Markov equivalence of chain graphs)** [Theorem 5.6 from [1]]

Two chain graphs  $G_1 = (V_1, E_1)$  and  $G_2 = (V_2, E_2)$  have the same Markov properties if and only if they have the same skeleton and the same complexes.

# Chapter 3

## LCD Algorithm

Here will be an overview of LCD Algorithm. To be written after the algorithm is described.

### 3.1. Decomposition of chain graphs

#### 3.1.1. Separation Trees

##### Definition 3.1.1. (Node Tree)

Let  $G = (V, E)$  be a graph and  $\mathcal{C} = \{C_1, \dots, C_k\}$  be a collection of distinct vertices sets such that  $\forall i \in \{1, 2, \dots, k\} C_i \subset V$ . A node tree is a graph which set of vertices are equal to  $\mathcal{C}$  and it contains undirected edges between every nodes  $C_i$  and  $C_j$ . Moreover for every edge  $e$  between  $C_i$  and  $C_j$  we add separator  $S(C_i, C_j) = C_i \cap C_j$  into set of nodes. Nodes  $C_i$  are displayed by triangle and separators are displayed by rectangles. Notation for node tree is  $\mathcal{T}(G, \mathcal{C})$ .

**TODO: Example of Node tree**

##### Definition 3.1.2. (Splitting Node Tree by separator)

Some definition.

##### Definition 3.1.3. (Separation tree)

For given chain graph  $G = (V, E)$  and node set  $\mathcal{C}$  we say that node tree  $\mathcal{T}(G, \mathcal{C})$  is a separation tree if

1.  $\cup_{C \in \mathcal{C}} C = V$  and
2. for any separator  $S = S(C_i, C_j)$  in node tree  $\mathcal{T}(G, \mathcal{C})$  with  $V_1$  and  $V_2$  as subtrees obtained by removing separator  $S$  we have

$$\langle V_1 \setminus S, V_2 \setminus S \mid S \rangle_G^{sep}$$
